

Zero-Drift, Rail-to-Rail I/O CMOS Operational Amplifiers**Features**

- * Low Offset Voltage: $\pm 1\mu\text{V}$ (TYP)
- * Input Offset Voltage Drift: $\pm 0.005\mu\text{V}/^\circ\text{C}$
- * Gain Bandwidth Product: 1.6MHz
- * Rail-to-Rail Input and Output
- * High Gain, CMRR, PSRR: 130dB
- * High Slew Rate: 0.7V/us
- * Low Noise: 1.3 μV p-p (0.01Hz~10Hz)
- * Low Power Consumption: 180uA/op amp
- * Overload Recovery Time: 2us
- * Low-Supply Voltage: +2.5 V to +5.5 V
- * No External Capacitors Required
- * Operating Temperature: -40°C to +125°C

General Description

The HCR8538/HCR8539 series of CMOS operational amplifiers use auto-zero techniques to simultaneously provide very low offset voltage ($5\mu\text{V}$ max) and near zero drift over time and temperature. This family of amplifiers has ultralow noise, offset and power.

This miniature, high-precision operational amplifiers offer high input impedance and rail-to-rail input and rail-to-rail output swing. With high gain-bandwidth product of 1.6MHz and slew rate of 0.7V/ μs .

Single or dual supplies as low as +2.5V ($\pm 1.25\text{V}$) and up to +5.5V ($\pm 2.75\text{V}$) may be used.

Applications

- * Temperature Sensors
- * Medical/Industrial Instrumentation
- * Pressure Sensors
- * Battery-Powered Instrumentation
- * Active Filtering
- * Weight Scale Sensor
- * Strain Gage Amplifiers
- * Power Converter/Inverter

The HCR8538/HCR8539 are specified for the extended industrial and automotive temperature range from -40°C to 125°C.

The HCR8538 single amplifier is available in SOT-23-5 packages, The HCR8539 dual amplifier is available in SOIC-8 (SOP-8) and MSOP-8 narrow surface mount packages.

	SOIC-8 (SOP8)	θ _{JA}	-	110	'C/W
	MSOP-8	θ _{JA}	-	170	'C/W
Storage Temperature Range		T _{STG}	-65 to +150		'C
Operating Temperature Range ^{note 2}		T _A	-40 to +125		'C
Junction Temperature ⁽⁵⁾		T _J	-40 to +150		'C
Lead Temperature (Soldering, 10s)		T _{LEAD}	260		'C
Human Body Model ESD Protection		ESD HBM	±5		KV
Machine Model ESD Protection		ESD MM	±400		V

Note 1. Stresses above these ratings may cause permanent damage. Exposure to absolute maximum conditions for extended periods may degrade device reliability. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those specified is not implied.

2. Input terminals are diode-clamped to the power-supply rails. Input signals that can swing more than 0.5V beyond the supply rails should be current-limited to 10mA or less.

3. Short-circuit to ground, one amplifier per package.

4. The package thermal impedance is calculated in accordance with JESD-51.

5. The maximum power dissipation is a function of T_J(MAX), R_{θJA}, and T_A. The maximum allowable power dissipation at any ambient temperature is PD = (T_J(MAX) - T_A) / R_{θJA}. All numbers apply for packages soldered directly onto a PCB.

Applications Information

The HCR8538/HCR8539 series op amps are unity-gain stable and free from unexpected output phase reversal. They use auto-zeroing techniques to provide low offset voltage and very low drift over time and temperature.

Good layout practice mandates use of a 0.1 μ F capacitor placed closely across the supply pins.

For lowest offset voltage and precision performance, circuit layout and mechanical conditions should be optimized. Avoid temperature gradients that create thermoelectric (Seebeck) effects in thermocouple junctions formed from connecting dissimilar conductors. These thermally-generated potentials can be made to cancel by assuring that they are equal on both input terminals.

- Use low thermoelectric-coefficient connections (avoid dissimilar metals).
- Thermally isolate components from power supplies or other heat-sources.
- Shield op amp and input circuitry from air currents, such as cooling fans.

Following these guidelines will reduce the likelihood of junctions being at different temperatures, which can cause thermoelectric voltages of 0.1 μ V/ $^{\circ}$ C or higher, depending on materials used.

Operating Voltage

The HCR8538/HCR8539 series op amps operate over a power-supply range of +2.5V to +5.5V ($\pm$ 1.25V to $\pm$ 2.75V). Supply voltages higher than 7V (absolute maximum) can permanently damage the amplifier.

Parameters that vary over supply voltage or temperature are shown in the Typical Characteristics section of this data sheet

Typical Applications

Bidirectional Current-Sensing

This single-supply, low-side, bidirectional current-sensing solution detects load currents from -1A to 1A. The single 'e-ended output spans from 110mV to 3.19V. This design uses the HCR8538/HCR8539 because of its low offset voltage and rail-to-rail input and output. One of the amplifiers is configured as a difference amplifier and the other provides the reference voltage.

Figure 21. Bidirectional Current-Sensing Schematic

Design Requirements

This solution has the following requirements:

- Supply voltage: 3.3V
- Input: -1 A to 1 A
- Output: 1.65V $\pm$ 1.54V (110mV to 3.19V)

Detailed Design Procedure

The load current, I_{LOAD} , flows through the shunt resistor (R_{SHUNT}) to develop the shunt voltage, V_{SHUNT} . The shunt voltage is then amplified by the difference amplifier which consists of U1A and R1 through R4. The gain of the difference amplifier is set by the ratio of R4 to R3.

Zero-Drift, Rail-to-Rail I/O CMOS Operational Amplifiers

Typical Applications(con.)

Bidirectional Current-Sensing(con.)

To minimize errors, set $R_2 = R_4$ and $R_1 = R_3$. The reference voltage, V_{REF} , is supplied by buffering a resistor divider using U1B. The transfer function is given by Equation 1.

$$V_{OUT} = V_{SHUNT} \times \text{Gain}_{\text{Diff_Amp}} + V_{REF}$$

Where

$$V_{SHUNT} = I_{LOAD} \times R_{SHUNT}$$

$$\text{Gain}_{\text{Diff_Amp}} = R_4 / R_3$$

$$V_{REF} = V_{CC} \times [R_6 / (R_5 + R_6)] \quad (1)$$

There are two types of errors in this design: offset and gain. Gain errors are introduced by the tolerance of the shunt resistor and the ratios of R_4 to R_3 and, similarly, R_2 to R_1 . Offset errors are introduced by the voltage divider (R_5 and R_6) and how closely the ratio of R_4/R_3 matches R_2/R_1 . The latter value impacts the CMRR of the difference amplifier, which ultimately translates to an offset error. Because this is a low-side measurement, the value of V_{SHUNT} is the ground potential for the system load. Therefore, it is important to place a maximum value on V_{SHUNT} . In this design, the maximum value for V_{SHUNT} is set to 100 mV. Equation 2 calculates the maximum value of the shunt resistor given a maximum shunt voltage of 100 mV and maximum load current of 1 A

$$R_{SHUNT(\text{Max})} = \frac{V_{SHUNT(\text{Max})}}{I_{LOAD(\text{Max})}} = \frac{100 \text{ mV}}{1 \text{ A}} = 100 \text{ m}\Omega \quad (2)$$

The tolerance of R_{SHUNT} is directly proportional to cost. For this design, a shunt resistor with a tolerance of 0.5% was selected. If greater accuracy is required, select a 0.1% resistor or better.

The load current is bidirectional; therefore, the shunt voltage range is -100 mV to 100 mV. This voltage is divided down by R_1 and R_2 before reaching the

operational amplifier, U1A. Take care to ensure that the voltage present at the noninverting node of U1A is within the common-mode range of the device. Therefore, it is important to use an operational amplifier, such as the HCR8538 and HCR8539 that has a common-mode range that extends below the negative supply voltage. Finally, to minimize offset error, note that the HCR8538, HCR8539 has a typical offset voltage of $\pm 3\mu\text{V}$ ($\pm 20\mu\text{V}$ maximum). Given a symmetric load current of -1A to 1A, the voltage divider resistors (R_5 and R_6) must be equal. To be consistent with the shunt resistor, a tolerance of 0.5% was selected. To minimize power consumption, 10k Ω resistors were used. To set the gain of the difference amplifier, the common-mode range and output swing of the HCR8538/HCR8539 must be considered. Equation 3 and Equation 4 depict the typical common-mode range and maximum output swing, respectively of the HCR8538, and HCR8539 given a 3.3V supply.

$$-100\text{mV} < V_{CM} < 3.4\text{V} \quad (3)$$

$$100\text{mV} < V_{OUT} < 3.2\text{V} \quad (4)$$

The gain of the difference amplifier can now be calculated as shown in Equation 5.

$$\text{Gain}_{\text{Diff_Amp}} = \frac{V_{OUT_Max} - V_{OUT_Min}}{R_{SHUNT} \times (I_{MAX} - I_{MIN})} = \frac{3.2 \text{ V} - 100 \text{ mV}}{100 \text{ m}\Omega \times [1 \text{ A} - (-1 \text{ A})]} = 15.5 \frac{\text{V}}{\text{V}}$$

The resistor value selected for R_1 and R_3 was 1k Ω . 15.4k Ω was selected for R_2 and R_4 because it is the nearest standard value. Therefore, the ideal gain of the difference amplifier is 15.4V/V

The gain error of the circuit primarily depends on R_1 through R_4 . As a result of this dependence, 0.1% resistors were selected. This configuration reduces the likelihood that the design requires a two-point calibration. A simple one-point calibration, if desired, removes the offset errors introduced by the 0.5% resistors.

Application Curve

Figure 22. Bidirectional Current-Sensing Circuit Performance: Output Voltage vs Input Current

Layout Guidelines

Attention to good layout practices is always recommend. Keep traces short. When possible, use a PCB ground plane with surface-mount components placed as close to the device pins as possible. Place a 0.1uF capacitor closely across the supply pins.

These guidelines should be applied throughout the analog circuit to improve performance and provide benefits such as reducing the EMI susceptibility.
