

1A Linear Li-ion Battery Charger IC**Features**

- Recommended operating voltage: 4.5V to 5.5V
- Absolute maximum input voltage: 12V
- Supports 9V hot plugging with an input RC snubber
- Overvoltage protection (OVP): 6.8V typical
- Programmable charging current up to 1A
- Preset 4.20V charging voltage with $\pm 1\%$ accuracy
- No external MOSFET, sense resistor or isolation diode required
- Constant-current/constant-voltage operation
- Charging, charge termination, no-battery and fault status indication
- Standby quiescent current: 1.0 μ A typical
- Supports charging activation of 0V batteries
- Battery reverse-polarity protection at BAT
- 2.9V trickle charging
- Automatic recharge
- Soft start limits inrush current
- Charging current regulation starts at a junction temperature of 165°C
- Operating temperature range: -40°C to +105°C
- Packages: SOP-8(EP), PDFN-3x3-8L

Applications

- Massage guns and electronic cigarettes
- Bluetooth headsets, GPS and wearable devices
- Digital cameras, mini speakers, electronic toys and other portable devices
- Hair clippers, shavers and various chargers

General Description

The HCR4056M series is a linear Li-ion battery charger IC with a 12V absolute maximum input voltage and a maximum charging current of 1.2A. It uses trickle-current, constant-current and constant-voltage charging. The charging voltage is set to 4.2V or 4.35V, and the charging current is set by an external resistor. After the battery voltage reaches 4.2V or 4.35V, charging stops when the current falls to C/10 of the programmed value, and the IC enters standby mode. When the supply is removed, the IC automatically enters low-power standby mode.

The HCR4056M is suitable for USB and adapter supplies. Its internal PMOSFET architecture and reverse-current blocking circuit eliminate the need for an external sense resistor or isolation diode.

Pin Descriptions

Pin No.	Name	Description
1	TS	Battery NTC temperature-sense input. Connect to ground when unused.
2	PROG	Programmable charging-current setting pin.
3	GND	Ground.
4	VCC	Power supply.
5	BAT	Connect to the positive battery terminal.
6	STDBY	Battery charge-complete indication output.
7	CHRG	Battery charging-status indication output.
8	CE	Chip enable, active high.

Selection Guide

Model	CE Active Level	Float Voltage	Trickle Current	Termination Current	Package
HCR4056MF	High	4.20V	C/5	C/10	SOP-8(EP), PDFN-3x3-8L
HCR4056MG	High	4.35V	C/5	C/10	SOP-8(EP), PDFN-3x3-8L

1A Linear Li-ion Battery Charger IC

Detailed Description and Application Information

Operating Principle

The HCR4056M is a linear charger for a single-cell Li-ion or lithium-polymer battery. The internal power MOSFET charges the battery in constant-current/constant-voltage mode. An external resistor programs the charging current, up to 1A. Two open-drain status outputs are provided: $\overline{\text{CHRG}}$ indicates charging and $\overline{\text{STDBY}}$ indicates charge completion. The internal power circuit automatically reduces charging current when the junction temperature exceeds 165°C. This permits maximum use of the charging capability without overheating and damaging the IC or external components. Input overvoltage protection protects the IC in complex input environments.

Normal Charging

A charging cycle begins when the V_{CC} pin voltage rises above the UVLO threshold and a 1%-accuracy programming resistor is connected between PROG and ground. If the BAT pin voltage is below the 2.9V trickle-charge threshold, the charger enters trickle-charge mode. In this mode, the HCR4056M supplies approximately C/5 of the programmed charging current to raise the battery voltage to a safe level. When BAT rises above the trickle-charge threshold, the charger enters constant-current mode and supplies a constant charging current to the battery. When BAT reaches the final float voltage of 4.2V or 4.35V, the IC enters constant-voltage mode and the charging current begins to decrease. The charging cycle ends when the current falls to C/10 of the programmed value.

Charging Current Programming

The charging current is programmed by a resistor connected between PROG and ground. The charging current is 1200 times the PROG output current. The programming resistor and charging current are calculated as follows:

$$R_{\text{PROG}} = \frac{1200}{I_{\text{BAT}}} \quad \text{or} \quad I_{\text{BAT}} = \frac{1200}{R_{\text{PROG}}}$$

The charging current from BAT can be determined at any time by monitoring the PROG voltage:

$$I_{\text{BAT}} = \frac{V_{\text{PROG}}}{R_{\text{PROG}}} \times 1200$$

When the programmed charging current exceeds 1A, the IC generates more heat and thermal protection reduces the charging current. Current measured under different environmental conditions may therefore differ from the theoretical value calculated by the formula. Select a suitable R_{PROG} for the application using the following recommended values:

R_{PROG} (k Ω)	I_{BAT} (mA)
1	1200
1.2	1000
2.4	500
5	240

Charge Termination

The charging cycle terminates when the current falls to C/10 of the programmed value after the final float voltage is reached. An internal filtered comparator monitors PROG to detect this condition. When the PROG voltage falls below 100mV (C/10), charging terminates and the HCR4056M enters standby mode, reducing the input supply current to approximately 100 μ A.

1A Linear Li-ion Battery Charger IC

Detailed Description and Application Information

Charging Status Indication

The HCR4056M has two open-drain status outputs, $\overline{\text{CHRG}}$ and $\overline{\text{STDBY}}$. $\overline{\text{CHRG}}$ is pulled low during charging and is high impedance in other states. When no battery is connected, $\overline{\text{CHRG}}$ outputs pulses to indicate that the battery is absent. With a $1\mu\text{F}$ external capacitor at the battery terminal, the $\overline{\text{CHRG}}$ flashing

period is approximately 0.1 to 0.8s. With a $10\mu\text{F}$ external capacitor at BAT, the flashing period is approximately 0.5 to 1s. Connect unused status outputs to ground. The complete indicator states are listed below:

Charging State	$\overline{\text{CHRG}}$ Level (LED)	$\overline{\text{STDBY}}$ Level (LED)
Charging	Low (on)	High impedance (off)
Fully charged	High impedance (off)	Low (on)
Input undervoltage, overvoltage or reversed battery	High impedance (off)	High impedance (off)
$10\mu\text{F}$ at BAT, no battery	Flashing, 0.5 to 1s	Low (on)
No other components at BAT	Continuously on	Continuously on

Thermal Regulation

When the IC temperature rises above 165°C , an internal thermal feedback loop reduces the programmed charging current. This prevents the HCR4056M from overheating and allows the upper limit of power handling on a given circuit board to be increased with less risk of damaging the IC.

Undervoltage Lockout

An internal undervoltage lockout circuit monitors the input voltage and holds the HCR4056M in shutdown until V_{CC} rises above the undervoltage lockout

threshold. The UVLO circuit keeps the charger in shutdown. If the UVLO comparator changes state, the charger does not leave shutdown until V_{CC} rises 100mV above the battery voltage.

Automatic Recharge

After the battery reaches the float voltage and the charging cycle terminates, the HCR4056M immediately monitors BAT. A new charging cycle begins when BAT falls below approximately 4.10V (4.20V float voltage). This keeps the battery nearly fully charged and eliminates the need to periodically initiate charging cycles.

1A Linear Li-ion Battery Charger IC

Detailed Description and Application Information

Battery Reverse-Polarity Protection

The HCR4056M includes Li-ion battery reverse-polarity protection. If a battery is connected in reverse to BAT, the IC shuts down and indicates a fault. The reversed battery leakage current is approximately 1mA. Correcting the battery connection automatically starts a charging cycle. If a reversed battery is removed, the capacitor at BAT remains at a negative potential, so the charging indicator does not immediately return to normal. Correctly connecting a battery automatically activates charging. Alternatively, wait for the negative charge on the BAT capacitor to discharge. When BAT rises above 0V, the IC displays the normal no-battery indication.

Charging Current Soft Start

The HCR4056M includes a soft-start circuit that minimizes inrush current at the beginning of a charging cycle. When a cycle starts, charging current rises from zero to the full-scale value in approximately 450 μ s, minimizing the transient current load on the supply during startup.

Input Overvoltage Protection (OVP)

The HCR4056M provides input overvoltage protection. When V_{CC} reaches approximately 6.8V, OVP shuts down the IC and stops battery charging. The IC resumes operation when the supply falls to approximately 6.2V.

Battery Temperature Monitoring

The HCR4056M integrates a battery temperature monitoring circuit to prevent battery damage caused by excessively high or low temperatures. It measures the voltage at TS, which is generated by the battery NTC thermistor and a resistor divider. The IC compares TS against two internal thresholds, V_{LOW} and V_{HIGH} , to determine whether the battery temperature is outside its normal range. V_{LOW} is fixed at $45\% \times V_{CC}$ and V_{HIGH} at $80\% \times V_{CC}$. If $V_{TS} < V_{LOW}$ or $V_{TS} > V_{HIGH}$, the battery is too hot or too cold and charging pauses. Charging continues when V_{TS} is between V_{LOW} and V_{HIGH} .

1A Linear Li-ion Battery Charger IC

Detailed Description and Application Information

Determining R_3 and R_4 for Temperature Sensing

Determine R_3 and R_4 from the battery temperature monitoring range and thermistor resistance, as illustrated below.

Assume the required battery temperature range is T_L to T_H , where $T_L < T_H$, and the battery uses a negative-temperature-coefficient (NTC) thermistor. R_{TL} is its resistance at T_L , and R_{TH} is its resistance at T_H ; therefore, $R_{TL} > R_{TH}$. At temperature T_L , the TS voltage is:

$$V_{TS} = \frac{R_4 \parallel R_{TH}}{R_3 + R_4 \parallel R_{TH}} \times V_{IN}$$

Using $V_{TS} = V_{HIGH} = K_2 \times V_{CC}$ ($K_2 = 0.8$) and $V_{TS} = V_{LOW} = K_1 \times V_{CC}$ ($K_1 = 0.45$) gives:

$$R_3 = \frac{R_{TL}R_{TH}(K_2 - K_1)}{(R_{TL} - R_{TH})K_2K_1}$$

$$R_4 = \frac{R_{TL}R_{TH}(K_2 - K_1)}{R_{TL}(K_1 - K_2K_1) - R_{TH}(K_2 - K_2K_1)}$$

Similarly, if the battery uses a positive-temperature-coefficient (PTC) thermistor:

$$R_3 = \frac{R_{TL}R_{TH}(K_2 - K_1)}{(R_{TH} - R_{TL})K_2K_1}$$

$$R_4 = \frac{R_{TL}R_{TH}(K_2 - K_1)}{R_{TH}(K_1 - K_2K_1) - R_{TL}(K_2 - K_2K_1)}$$

These equations show that the required temperature range is independent of V_{CC} and depends only on R_3 , R_4 , R_{TH} and R_{TL} . R_{TH} and R_{TL} can be obtained from the battery documentation or by measurement.

If only one temperature limit is required, such as overtemperature protection, R_4 may be omitted and only R_3 used.

Note: Refer to the application circuit for the positions of R_3 and R_4 .

Input/Output Capacitor and Resistor Selection and PCB Layout

To ensure reliable operation under various conditions and prevent damage from voltage spikes and glitches, use an RC filter at the input (refer to the typical application circuit). Capacitor values: $C_1 = 105$, $C_2 = 104$. Place the capacitors as close as possible to the IC pins on the PCB.

Recommended resistor values: R_1 and $R_2 = 1k\Omega$. These resistors must not be omitted, to prevent incorrect LED indications.

Solder the exposed pad (EP) on the bottom of the IC securely to the PCB. Add vias in the bottom thermal area and preferably use a large copper area for heat dissipation. A multilayer PCB with sufficient vias improves heat dissipation. Poor heat dissipation may reduce charging current through thermal protection. Suitable vias in the rear thermal area also facilitate hand soldering: solder can be fed through the vias from the rear to securely solder the thermal pad.

For high-current charging applications above 1000mA, add a heat-dissipation resistor at V_{IN} to shorten charging time. Select a suitable resistance from 0.2Ω to 0.4Ω according to the application.

Conditions of Soldering and Storage

Recommended Condition of Reflow Soldering

Recommended peak temperature is over 245°C. If peak temperature is below 245°C, you may adjust the following parameters:

- Time length of peak temperature (longer)
- Time length of soldering (longer)
- Thickness of solder paste (thicker)

Conditions of Hand Soldering

- Temperature: 300°C
- Time: 3s max
- Times: one time

Storage Conditions

- Temperature: 5 to 40°C
- Humidity: 30 to 80% RH
- Recommended period: One year after manufacturing
